Hyper Box

You live in the universe X where all the physical laws and constants are different from ours. For example, all of their objects are N-dimensional.

The living beings of the universe X want to build an *N* -dimensional monument. We can consider this *N* dimensional monument as an *N*-dimensional hyper-box, which can be divided into some *N dimensional* hyper- cells.

The length of each of the sides of a hyper-cell is one. They will use some *N* -dimensional bricks (or hyper-bricks) to build this monument.

But the length of each of the N *sides* of a brick cannot be anything other than Fibonacci numbers. A Fibonacci sequence is given below:

1, 2, 3, 5, 8, 13, 21, . . .

As you can see each value starting from 3 is the sum of previous 2 values. So, for $N = 3$ they can use bricks of sizes (2,5,3), (5,2,2) etc. but they cannot use bricks of size (1,2,4) because the length 4 is not a Fibonacci number. Now given the length of each of the dimension of the monument determine the minimum number of hyper-bricks required to build the monument. No two hyper-bricks should intersect with each other or should not go out of the hyper-box region of the monument. Also, none of the hyper-cells of the monument should be empty.

Input

First line of the input file is an integer T ($1 \leq T \leq 100$) which denotes the number of test cases. Each test case starts with a line containing N ($1 \leq N \leq 15$) that denotes the dimension of the monument and the bricks. Next line contains N integers the length in each dimension. Each of these integers will be between 1 and 2000000000 inclusive.

Output

For each test case output contains a line in the format Case x: M where x is the case number (starting from 1) and M is the minimum number of hyper-bricks required to build the monument.

Sample Input

```
2
2
4 4
3
5 7 8
```

Sample Output

```
Case 1: 4
Case 2: 2
```
